

The Moving Moon
By: Christopher DiPoalo

Do you know what the moon is? Do you know how the moon shines? Do you know why the moon looks so big? Well I can answer them questions for you. The moon is not a planet it is a star. The moon looks so big because it is earths closest friend In space. The moon is so bright because it uses the Suns Rays then it reflects that light onto the part of earth that is in nighttime. The moon has not very powerful gravity and atmosphere like if you were to stand on a scale on the moon you would only weight one-sixth of your weight on earth. The moon also has these giant holes called craters that people believe we're made by rocks crashing into the moon a long time ago. The moon is a fascinating and I hope you study about the moon.
